FLOOD INSURANCE STUDY NUMBER

28075CV000A

NOTICE TO

FLOOD INSURANCE STUDY USERS

Communities participating in the National Flood Insurance Program (NFIP) have established repositories of flood hazard data for floodplain management and flood insurance purposes. This Flood Insurance Study (FIS) may not contain all data available within the repository. It is advisable to contact the community repository for any additional data.

Part or all of this FIS may be revised and republished at any time. In addition, part of this FIS may be revised by the Letter of Map Revision process, which does not involve republication or redistribution of the FIS report. It is, therefore, the responsibility of the user to consult with community officials and to check the community repository to obtain the most current FIS components.

Initial Countywide FIS Effective Date: September 29, 1989

Revised Countywide FIS Dates: August 16, 1995  
March 21, 2000

**FLOOD INSURANCE STUDY  
LAUDERDALE COUNTY, MISSISSIPPI AND INCORPORATED AREAS**

**1.0 INTRODUCTION**

1.1 Purpose of Study

This Flood Insurance Study (FIS) revises and updates a previous FIS and/or Flood Insurance Rate Maps (FIRMs) in the geographic area of Lauderdale County, Mississippi, including the incorporated areas of the City of Meridian, the Town of Marion, and the Unincorporated Areas of Lauderdale County (hereinafter referred to collectively as Lauderdale County), and aids in the administration of the National Flood Insurance Act of 1968 and the Flood Disaster Protection Act of 1973.

This study has developed flood risk data for various areas of the community that will be used to establish actuarial flood insurance rates. This information will also be used by Lauderdale County to update existing floodplain regulations as part of the Regular Phase of the National Flood Insurance Program (NFIP). And by local and regional planners to further promote sound land use and floodplain development. Minimum floodplain management requirements for participation in the NFIP are set forth in the Code of Federal Regulations at 44 CFR, 60.3.

In some States or communities, floodplain management criteria or regulations may exist that are more restrictive or comprehensive than the minimum Federal requirements. In such cases, the more restrictive criteria take precedence and the State (or other jurisdictional agency) will be able to explain them.

1.2 Authority and Acknowledgments

The sources of authority for this Flood Insurance Study are the National Flood Insurance Act of 1968 and the Flood Disaster Protection Act of 1973.

The hydrologic and hydraulic analyses for the initial September 29, 1989 countywide FIS were performed by the U.S. Army Corps of Engineers (USACE), Mobile District, for the Federal Emergency Management Agency (FEMA), under Inter-Agency Agreement No. EMW-85-E-1822. That work was completed in March 1987.

The hydrologic and hydraulic analyses for the August 16, 1995 FIS revision of Sowashee Creek, Gallagher Creek, Magnolia Creek, Nanabe Creek, Robbins Branch, and Shear's Branch were prepared by the USACE, Mobile District. That work was completed in January 1993.

The hydrologic and hydraulic analyses for the March 21, 2000 revision of Gallagher Creek, Magnolia Creek, Robbins Branch, Harbour Creek, and Newell Branch were prepared by the USACE, Mobile District, for FEMA, under Inter-Agency Agreement No. EMW-94-E-4371. This work was completed in February 1998.

The hydrologic and hydraulic analyses for this countywide revision were performed by the State of Mississippi for FEMA. This study was completed in September 2008 under Contract No. EMA-2005-CA-5215.

Base map information shown on the FIRM was provided in digital format by the State of Mississippi. The digital orthoimagery was photogrammetrically compiled at a scale of 1:400 from aerial photography dated March 2006.

The digital FIRM was produced using the State Plane Coordinate System, Mississippi East, FIPS ZONE 2301. The horizontal datum was the North American Datum of 1983, GRS 80 spheroid. Distance units were measured in U.S. feet.

### 1.3 Coordination

An initial Consultation Coordination Officer's (CCO) meeting is held with representatives from FEMA, the community, and the study contractor to explain the nature and purpose of a FIS, and to identify the streams to be studied by detailed methods. A final CCO meeting is held with the same representatives to review the results of the study.

For the September 29, 1989 countywide FIS, the initial CCO meeting was held on June 13, 1985. The final CCO meeting was held on October 17 & 18, 1988.

For the August 16, 1995 revision, the City of Meridian, the Town of Marion, and the unincorporated areas of Lauderdale County were notified of the revision by FEMA in the letter dated July 21, 1993. A final CCO meeting was held on August 9, 1994.

For the March 21, 2000 revision, an initial CCO meeting was held on August 13, 1993.

For this countywide revision, an initial CCO meeting was held on September 9, 2005. This meeting was attended by the representatives of the City of Meridian, the Town of Marion, Lauderdale County, Mississippi Emergency Management Agency (MEMA), Mississippi Department of Environmental Quality (MDEQ) and Mississippi Geographic Inc. LLC (MGI). Coordination with county officials and Federal, State, and regional agencies produced a variety of information pertaining to floodplain regulations, available community maps, flood history, and other hydrologic data. All problems raised in the meetings have been addressed.

## 2.0 **AREA STUDIED**

### 2.1 Scope of Study

This FIS covers the geographic area of Lauderdale County, Mississippi, including the incorporated communities listed in Section 1.1.

#### **September 29, 1989 Countywide FIS**

All or portions of Bailey Branch, Nanabe Creek, Gallagher Creek, Okatibbee Creek, Gunn Branch, Okatibbee Creek Tributary, Harper Creek, Robbins Branch, Harper Creek Tributary, Shear's Branch, Loper Creek, Sowashee Creek, Magnolia Creek, and Suqualena Creek were studied by Detailed methods.

**August 16, 1995 Revision**

Revised analyses were included for the flooding sources shown in Table 1, “Scope of Revision for August 16, 1995, FIS”.

TABLE 1 – SCOPE OF REVISION FOR AUGUST 16, 1995, FIS

<u>Stream</u>	<u>Limits of Revised or New Detailed Study</u>
*Gallagher Creek	From its confluence with Sowashee Creek to a point approximately 500 feet upstream of the Norfolk Southern Railroad.
*Magnolia Creek	From its confluence with Sowashee Creek to the Illinois Central Railroad.
*Okatibbee Creek	From a point approximately 1.16 miles downstream of the confluence of Burwell Creek to a point approximately 0.24 mile downstream of the confluence.
*Nanabe Creek	From its confluence with Sowashee Creek to a point approximately 1.3 miles upstream.
Sowashee Creek	From a point approximately 2,600 feet above its confluence with Okatibbee Creek to the Second County Road bridge upstream of the U.S. Route 45 Bypass.
*Robbins Branch	From its confluence with Sowashee Creek to U.S. Route 45.
*Shear’s Branch	From its confluence with Sowashee Creek to a point approximately 0.2 mile upstream.
*Backwater effects from Sowashee Creek have been adjusted based on the Detailed analyses of Sowashee Creek.	

**March 21, 2000 Revision**

All or portions of the flooding sources listed in Table 2, “Streams Studied by Detailed Methods,” were studied by Detailed methods. Limits of Detailed study are indicated on the Flood Profiles (Exhibit 1) and on the FIRM (Exhibit 2).

TABLE 2. STREAMS STUDIED BY DETAILED METHODS

Bailey Branch	Loper Creek	Robbins Branch
Gallagher Creek	Magnolia Creek	Shear’s Branch
Gunn Branch	Nanabe Creek	Sowashee Creek
Harbour Creek	Newell Branch	Suqualena Creek
Harper Creek	Okatibbee Creek	
Harper Creek Tributary	Okatibbee Creek Tributary	

For the March 21, 2000 countywide revision, the streams shown in Table 3, “Scope of Revision for March 21, 2000, FIS,” were restudied or newly studied by Detailed methods. This revision also incorporates a Letter of Map Revision (LOMR), dated September 30, 1999. This LOMR reflects more up-to-date hydrologic and hydraulic analyses along Sowashee Creek. The subject area is located from a point approximately 1,000 feet downstream of Hawkins Crossing Road (U.S. Route 45), to a point approximately 2,600 feet upstream of the confluence with Okatibbee Creek.

TABLE 3 - SCOPE OF REVISION FOR MARCH 21, 2000, FIS

<u>Stream</u>	<u>Limits of Revised New Detailed Study</u>
Gallagher Creek	From its mouth to a point approximately 50 feet upstream of State Route 493.
Harbour Creek	From its mouth to a point approximately 1,025 feet upstream of Windover Circle.
Magnolia Creek	From its mouth to a point approximately 100 feet upstream of 36 <sup>th</sup> Street.
Newell Branch	From its mouth to just downstream of 63 <sup>rd</sup> Street.
Robbins Branch	From its mouth to a point approximately 2,800 feet upstream of 52 <sup>nd</sup> Court.

**This Countywide Revision Analyses**

In this FIS revision, some streams have names other than those used in previously printed FISs. Details of these name changes are listed in the following tabulation:

<u>Community</u>	<u>Old Name</u>	<u>New Name</u>
Lauderdale County	Harper Creek Tributary	Harper Creek Tributary 1
Lauderdale County	Okatibbee Creek Tributary	Okatibbee Creek Tributary 5

For this countywide FIS revision, limited detailed analyses were used to study those areas having a low development potential or minimal flood hazards. The scope and methods of study were proposed to, and agreed upon, by FEMA and the State of Mississippi. For this FIS revision, Table 4, “Streams Studied by Limited Detailed Methods,” lists the streams which were newly studied by Limited Detailed methods.

TABLE 4 – STREAMS STUDIED BY LIMITED DETAILED METHODS

<u>Stream</u>	<u>Limits of Revision/New Limited Detailed Study</u>
Mclemore Branch	From approximately 500 feet upstream of the confluence with Newell Creek to Old Country Club Road.

TABLE 4 – STREAMS STUDIED BY LIMITED DETAILED METHODS - continued

<u>Stream</u>	<u>Limits of Revision/New Limited Detailed Study</u>
Sowashee Creek Tributary 8	From its confluence with Sowashee Creek Tributary 12 to 360 feet downstream of Hillview Drive.
Sowashee Creek Tributary 10	From approximately 50 feet downstream of Highway 45 to approximately 500 feet upstream of Cotton Gin Road.
Sowashee Creek Tributary 11	From approximately 500 feet upstream of the confluence with Sowashee Creek Tributary 10 to approximately 600 feet upstream of Ponta Hills Road.

Also, floodplain boundaries of streams that have been previously studied by detailed methods were redelineated based on up-to-date topographic information.

All remaining flooding sources in the county were studied by approximate methods, and are the basis of the revised Zone A mappings included on the FIRMs.

## 2.2 Community Description

Lauderdale County is located in east-central Mississippi, and is bordered by Kemper County on the north, Newton County on the west, Clarke County on the south, and Sumter and Choctaw Counties. Alabama on the east. The City of Meridian, the county seat, is approximately 90 miles east of the City of Jackson. Lauderdale County is served by Interstate Routes 20 and 59; U.S. Routes 11, 45, and 80; State Routes 19 and 39; the Illinois Central Railroad; the Norfolk Southern Railway; and the Meridian & Bigbee Railroad. The 2000 population of Lauderdale County was reported to be 78,161 (Reference 1).

Topography in the area consists of gently rolling hills with elevations ranging from 270 feet national Geodetic Vertical Datum of 1929 (NGVD) to approximately 550 feet NGVD. The hilly terrain to the north, east, and west of the study area has a pronounced effect on the temperature pattern at Meridian.

Lauderdale County's climate is mild, with an average summer temperature of 79.8 degrees Fahrenheit (°F), and an average winter temperature of 48.4 °F. Extreme temperatures of -7 °F and 105 °F have been recorded at Meridian (Reference 2).

Precipitation is evenly distributed throughout the year. March is the wettest month, averaging 6.0 inches of rainfall, and October is the driest, averaging 2.4 inches. Annual precipitation averages 56.7 inches (Reference 3).

The Okatibbee Creek floodplain is relatively undeveloped, with only a few structures in the area. The floodplains of Sowashee Creek, Gallagher Creek, Magnolia Creek, Robbins Branch, Nanabe Branch, and Loper Creek have yielded to urban expansion, including commercial, industrial, and residential development and public utilities.

Numerous city streets, state highways, and railway lines cross the floodplains. Economic development within the study area continues to expand.

### 2.3 Principal Flood Problems

Significant flooding occurs in the low-lying areas along Okatibbee Creek and its tributaries and along Sowashee Creek and its tributaries. Major floods occurred on Okatibbee Creek and its tributaries in 1961, 1976, and 1979. Major floods occurred on Sowashee Creek and its tributaries in 1951, 1961, 1964, 1972, 1974, and 1979. Parts of Sowashee Creek floodplain have been filled in and developed in recent years, leading to increased flooding potential along some parts of the stream. Floods can occur in the City of Meridian any time during the year, but most frequent flooding occurs during late summer or early fall caused by brief intense storms.

### 2.4 Flood Protection Measures

The Okatibbee Dam, built in 1968 and operated by the USACE, is 37.65 miles upstream of the Okatibbee Creek mouth. In the City of Meridian, the dam provides reductions in the 10-, 2-, 1-percent-annual-chance floods of 2.1 feet, 1.4 feet, and 1.2 feet, respectively.

During World War II, the USACE constructed a levee in southern Meridian that joins high ground and encloses Key Field. The levee would be overtopped by the 0.02-percent-annual-chance flood on Okatibbee Creek and by the 2-percent-annual-chance flood on Sowashee Creek.

The USACE completed the Sowashee Creek Flood Control Project in December 1992. The project consisted of clearing and snagging the channel and overbanks; channel modifications; bridge modifications and relocations; and control structures. The project extends from the mouth of the stream to Hawkins Crossing Road. The Soil Conservation Service (SCS, now known as the Natural Resources Conservation Service, NRCS) has completed three flood control structures in the Sowashee Creek drainage basin that help to reduce the flood elevations along Sowashee Creek. These existing NRCS structures were considered for this FIS. The NRCS plans to construct additional flood retarding structures in the upper reaches of the Sowashee Creek drainage basin when funding becomes available; these structures were not considered for this FIS.

Portions of Gallagher Creek, Magnolia Creek, and Robbins Branch have been modified. Channel modifications range from grading to concrete lining. The lower portion of Gallagher Creek was modified by the construction of a project built by the NRCS.

## 3.0 **ENGINEERING METHODS**

For the flooding sources studied by detailed methods in the community, standard hydrologic and hydraulic study methods were used to determine the flood hazard data required for this FIS. Flood events of a magnitude that are expected to be equaled or exceeded once on the average during any 10-, 50-, 100-, or 500-year period (recurrence interval) have been selected as having special significance for floodplain management and for flood insurance rates. These events, commonly termed the 10-, 50-, 100-, and 500-year floods, have a 10-, 2-, 1-, and 0.2-percent chance, respectively, of being equaled or exceeded during any year. Although the recurrence interval represents the long-term, average period between floods of a specific

magnitude, rare floods could occur at short intervals or even within the same year. The risk of experiencing a rare flood increases when periods greater than 1 year are considered. For example, the risk of having a flood that equals or exceeds the 1-percent-annual-chance flood in any 50-year period is approximately 40 percent (4 in 10); for any 90-year period, the risk increases to approximately 60 percent (6 in 10). The analyses reported herein reflect flooding potentials based on conditions existing in the community at the time of completion of this study. Maps and flood elevations will be amended periodically to reflect future changes.

### 3.1 Hydrologic Analyses

Hydrologic analyses were carried out to establish peak discharge-frequency and peak elevation-frequency relationships for each flooding source studied by Detailed methods affecting the community.

#### **September 29, 1989 Countywide Analyses**

Flow frequencies for uncontrolled drainage areas along the detailed studied streams were determined by one of two methods. For drainage areas larger than four square miles, flows were developed using regional relationships taken from a USACE environmental impact statement (Reference 4). Methodology presented in that report was developed from regional data on drainage areas of 15 square miles or more in the Pascagoula River basin. For drainage areas smaller than four square miles, flows were determined using the regional equations presented in the U.S. Geological Survey's (USGS) "Flood Frequency of Mississippi Streams" (Reference 5).

#### **August 16, 1995 Revision Analyses**

Discharges for locations from the mouth of Sowashee Creek to below the confluence with Nanabe Creek were determined by using the existing conditions discharges Table II-3, "Peak Discharges at Selected Locations, Project Conditions," in the USACE report entitled Sowashee Creek, Meridian, Mississippi, Design Memorandum No. 1, dated April 1986 (Reference 6). These discharges included adjustments for expected probability. The expected probability adjustments were removed from these estimates by reversing the procedure described in Bulletin 17B (Reference 7). Table II-1 Bulletin 17B was entered at  $P_N$ , the expected probability values from Table II-3, and the number of years of record at the gage,  $N=80$ . The values of  $P$ , the exceedance frequencies without the adjustments, were then interpolated from the table header. The discharges from the table were then plotted at these frequencies and the discharges for the 10-, 2-, 1-, and 0.2-percent-annual-chance flood events were interpolated from the graphs.

Discharges for locations on Sowashee Creek above the confluence with Nanabe Creek were determined by using regional frequency relationships developed by the Mobile District and described in the USACE report entitled Sowashee Creek, Meridian, Mississippi, Phase 1 General Design Memorandum and Environmental Impact Statement (Reference 4).

Discharge data were obtained from the NRCS for each of the reservoirs. An analysis was made to determine the effects of these reservoirs on the discharges on Sowashee Creek from the mouth to the county road crossing at Marion. Although these structures create relatively large reductions on the tributaries on which they are located, their location in

the drainage basin and the size of the areas they control, compared to the size of the Sowashee Creek drainage area, almost eliminates the effect they have on the discharges on Sowashee Creek. However, combined with the other 10 structures in the total basin plan, the effect could be a significant reduction in the discharges.

The USGS completed a regional study in Mississippi and published a report, Water-Resources Investigation Report 91-4037 (Reference 8). The regional equations from this study produced discharges that were considerably lower than those in the USACE report. The USACE conducted a search of the data compiled by the USGS, which revealed that the period of record at the Sowashee Creek gage ran from 1939 to 1988, with peaks from 1946 to 1948 missing. Two floods, February 1936 and April 1938, occurred prior to the systematic record and were higher than any flood in the systematic record. In addition, the 1936 flood was listed as the highest flood since 1900. These two floods only had peak stages listed in the database, and were not included in the USGS study. The USACE study included estimated discharges for these two flood events. By including these events the historic gage record could be extended to 1900. Omitting these two floods, especially the 1936 flood, may underestimate the frequency curve. Therefore, for purposes of this study, the USACE decided not to use the USGS regional study and to use its own study, which included these estimated peaks.

**March 21, 2000 Revision Analyses**

Discharges were determined using USGS regional equations from Flood Characteristics of Mississippi Streams (Reference 9). Drainage areas were determined from 1:24,000 quadrangle maps.

**This Revision Analyses**

Peak discharges for the streams studied by Limited Detailed methods were calculated based on USGS regional regression equations (Reference 9). For the discharges calculated based on regional regression equations, the rural regression values were updated to reflect urbanization as necessary.

A summary of the drainage area-peak discharge relationships for the streams studied by Detailed and Limited Detailed methods is shown in Table 5, "Summary of Discharges."

### 3.2 Hydraulic Analyses

Analyses of the hydraulic characteristics of flooding from the sources studied were carried out to provide estimates of the elevations of floods of the selected recurrence intervals. Users should be aware that flood elevations shown on the FIRM represent rounded whole-foot elevations and may not exactly reflect the elevations shown on the Flood Profiles or in the Floodway Data Tables in the FIS report. Flood elevations shown on the FIRM are primarily intended for flood insurance rating purposes. For construction and/or floodplain management purposes, users are encouraged to use the flood elevation data presented in this FIS report in conjunction with the data shown on the FIRM.

#### **September 29, 1989 Countywide Analyses**

Cross sections were obtained from field surveys supplemented by sections from previously published topographic maps of the City of Meridian (Reference 10).

Locations of selected cross sections used in the hydraulic analyses are shown on the Flood Profiles (Exhibit 1). For stream segments for which a floodway was computed (Section 4.2), selected cross-section locations are also shown on the FIRM (Exhibit 2).

Water-surface elevations of floods of the selected recurrence intervals were computed using the USACE HEC-2 step-backwater computer program (Reference 11).

Roughness factors (Manning's "n") were chosen by engineering judgment and based on field observations of the stream and floodplain areas, and comparing water-surface profiles with rating curves at gages on Okatibbee Creek. The channel and "n" values for Sowashee Creek ranged from 0.020 to 0.045, and the overbank "n" values ranged from 0.060 to 20.0; the overbank "n" value of 20.0 was used to represent ineffective flow in the HEC-2 model for Sowashee Creek. The channel "n" values for all other flooding sources studied by detailed methods ranged from 0.038 to 0.060 and the overbank "n" values ranged from 0.070 to 0.150.

#### **August 16, 1995 Revision Analyses**

Cross sections for Sowashee Creek from the mouth to Hawkins Crossing Road were obtained from field surveys. Right and left overbank cross-section geometry was obtained from topographic maps at a scale of 1"=200' with a contour interval of 2 feet (Reference 12). Cross sections for Sowashee Creek from Hawkins Crossing Road to the second county road above Highway 45 By-Pass were taken from the previously published September 29, 1989, FIS for Lauderdale County (Reference 13). All bridges, dams, and culverts were field surveyed to obtain elevation data and structural geometry.

Locations of selected cross sections used in the hydraulic analyses are shown on the Flood Profiles (Exhibit 1). For stream segments for which a floodway was computed (Section 4.2), selected cross-section locations are also shown on the FIRM (Exhibit 2).

Starting water-surface elevations for Sowashee Creek were obtained from a USACE design memorandum (Reference 6). Flood profiles were drawn showing computed water-surface elevations for floods of the selected recurrence intervals.

Roughness factors (Manning's "n") were chosen by engineering judgment and based on field observations of the stream and floodplain areas, and comparing water-surface profiles with rating curves at gages on Okatibbee Creek. The channel and "n" values for Sowashee Creek ranged from 0.020 to 0.045, and the overbank "n" values ranged from 0.060 to 20.0; the overbank "n" value of 20.0 was used to represent ineffective flow in the HEC-2 model for Sowashee Creek. The channel "n" values for all other flooding sources studied by detailed methods ranged from 0.038 to 0.060 and the overbank "n" values ranged from 0.070 to 0.150.

Areas of the community protected by levees were subject to potential risk due to possible failure or overtopping of the levee. Those areas were delineated by applying the 1-percent-annual-chance elevation determined from the "levee in place" analysis.

### **March 21, 2000 Revision Analyses**

Cross section geometry utilized in the model was obtained from contour mapping field surveys, and construction drawings. Structural geometry and elevation data for bridges within the study reaches were obtained from field surveys and construction drawings.

The profiles of the selected recurrence interval floods were computed with standard step backwater math models using the USACE HEC-2 computer program (Reference 11). Starting water-surface elevations for streams studied were developed by the slope-area option of the HEC-2 model. Channel and overbank roughness factors (Manning's "n") used in the hydraulic computations were chosen by engineering judgment from aerial photos and field inspection of the channels and floodplain areas. The channel "n" values used for this study ranged from 0.015 to 0.07. The overbank "n" values ranged from 0.080 to 0.15 except in areas containing non-effective flow.

Maps of the study area, at a scale of 1 inch equals 200 feet with a contour interval of five feet, were used for the topographic data. The maps are based on City of Meridian topographic maps (Reference 10).

The hydraulic analyses for this FIS are based on unobstructed flow. The flood elevations shown on the profiles are thus considered valid only if hydraulic structures remain unobstructed, operate properly, and do not fail.

### **This Revision Analyses**

Cross section geometries were obtained from a combination of terrain data and field surveys. Bridges and culverts located within the Limited Detailed study limits were field surveyed to obtain elevation data and structural geometry.

Downstream boundary conditions for the hydraulics models were set to normal depth using a starting slope calculated from values taken from topographic data, or where applicable, derived from the water-surface elevations of existing effective flood elevations or recalculated flood elevations. Water-surface profiles were computed through the use of USACE HEC-RAS version 3.1.2 computer program (Reference 14). The model was run for the 1-percent-annual-chance storm for the Limited Detailed and approximate studies.

Manning’s “n” values used in the hydraulic computations for both channel and overbank areas were based on recent digital orthophotography and field investigations.

Table 6, “Summary of Roughness Coefficients,” shows the ranges of the channel and overbank roughness factors used in the computations for the streams studied by Detailed methods and streams newly studied by Limited Detailed methods.

TABLE 6 - SUMMARY OF ROUGHNESS COEFFICIENTS

<u>Stream</u>	<u>Channel “n”</u>	<u>Overbank “n”</u>
Bailey Branch	0.015-0.07	0.080-0.15

Newell Branch	0.015-0.07	0.080-0.15
Okatibbee Creek	0.015-0.07	0.080-0.15
Okatibbee Creek Tributary 5	0.015-0.07	0.080-0.15
Robbins Branch	0.015-0.07	0.080-0.15
Shear’s Branch	0.015-0.07	0.080-0.15
Sowashee Creek	0.015-0.07	0.080-0.15
Sowashee Creek Tributary 8	0.046-0.051	0.05-0.15
Sowashee Creek Tributary 10	0.05-0.055	0.09-0.15
Sowashee Creek Tributary 11	0.035-0.05	0.07-0.15
Suqualena Creek	0.015-0.07	0.080-0.15

The hydraulic analyses for this study were based on unobstructed flow. The flood elevations shown on the Flood Profiles (Exhibit 1) are thus considered valid only if hydraulic structures remain unobstructed, operate properly, and do not fail.

All elevations are referenced to NAVD88.

### 3.3 Vertical Datum

All FIS reports and FIRMS are referenced to a specific vertical datum. The vertical datum provides a starting point against which flood, ground, and structure elevations can be referenced and compared. Until recently, the standard vertical datum in use for newly created or revised FIS reports and FIRMS was the National Geodetic Vertical Datum of 1929 (NGVD29). With the finalization of the North American Vertical Datum of 1988 (NAVD88), many FIS reports and FIRMS are being prepared using NAVD88 as the referenced vertical datum.

Qualifying bench marks within a given jurisdiction that are cataloged by the National Geodetic Survey (NGS) and entered into the National Spatial Reference System (NSRS)

as First or Second Order Vertical and have a vertical stability classification of A, B, or C are shown and labeled on the FIRM with their 6-character NSRS permanent identifier.

Bench marks cataloged by the NGS and entered into the NSRS vary widely in vertical stability classification. NSRS vertical stability classifications are as follows:

Stability A: Monuments of the most reliable nature, expected to hold position/elevation well (e.g., mounted in bedrock)

Stability B: Monuments which generally hold their position/elevation well (e.g., concrete bridge abutment)

Stability C: Monuments which may be affected by surface ground movements (e.g., concrete monuments below frost line)

Stability D: Mark of questionable or unknown vertical stability (e.g., concrete monument above frost line, or steel witness post)

All flood elevations shown in this FIS report and on the FIRM are referenced to NAVD88. Structure and ground elevations in the community must, therefore, be referenced to NAVD88. It is important to note that adjacent communities may be referenced to NGVD29. This may result in differences in Base Flood Elevations (BFEs) across the corporate limits between the communities.

The elevations shown in the FIS report and on the FIRM for Lauderdale County are referenced to NAVD88. Ground, structure, and flood elevations may be compared and/or referenced to NGVD29, add 0.04 feet to the NGVD29 elevation. The 0.04 feet value is an average for the entire county. The BFEs shown on the FIRM represent whole-foot rounded values. For example, a BFE of 12.4 feet will appear as 12 feet on the FIRM and 12.6 feet as 13 feet. Users who wish to convert the elevations in this FIS report to NGVD29 should apply the stated conversion factor to elevations shown on the Flood Profiles and supporting data tables in the FIS report, which are shown at a minimum to the nearest 0.1 foot.

To obtain current elevation, description, and/or location information for bench marks shown on the FIRM for this jurisdiction, or for information regarding conversion between the NGVD29 and NAVD88, see the FEMA publication entitled *Converting the National Flood Insurance Program to the North American Vertical Datum of 1998* (FEMA, June 1992), or contact the Vertical Network Branch, National Geodetic Survey, Coast and Geodetic Survey, National Oceanic and Atmospheric Administration, Rockville, Maryland 20910 (Internet address <http://www.ngs.noaa.gov>).

Temporary vertical monuments are often established during the preparation of a flood hazard analysis for the purpose of establishing local vertical control. Although these monuments are not shown on the FIRM, they may be found in the Technical Support Data Notebook associated with the FIS report and FIRM for this community. Interested individuals may contact FEMA to access these data.

## **4.0 FLOODPLAIN MANAGEMENT APPLICATIONS**

The NFIP encourages State and local governments to adopt sound floodplain management programs. To assist in this endeavor, each FIS provides 1-percent-annual-chance floodplain data, which may include a combination of the following: 10-, 2-, 1-, and 0.2-percent-annual-chance flood elevations; delineations of the 1-percent and 0.2-percent-annual-chance floodplains; and 1-percent-annual-chance floodway. This information is presented on the FIRM and in many components of the FIS report, including Flood Profiles, Floodway Data Table, and Summary of Stillwater Elevations Table. Users should reference the data presented in the FIS report as well as additional information that may be available at the local community map repository before making flood elevation and/or floodplain boundary determinations.

### **4.1 Floodplain Boundaries**

To provide a national standard without regional discrimination, the 1-percent-annual-chance flood has been adopted by FEMA as the base flood for floodplain management purposes. The 0.2-percent-annual-chance flood is employed to indicate additional areas of flood risk in the community. For each stream studied by detailed methods, the 1- and 0.2-percent-annual-chance floodplain boundaries have been delineated using the flood elevations determined at each cross section.

For this countywide revision, 10 meter Digital Elevation Model (DEM) data from the USGS were used to delineate the floodplain boundaries. The 1- and 0.2-percent-annual-chance floodplain boundaries are shown on the FIRM (Exhibit 2). On this map, the 1-percent-annual-chance floodplain boundary corresponds to the boundary of the areas of special flood hazards (Zones A and AE), and the 0.2-percent-annual-chance floodplain boundary corresponds to the boundary of areas of moderate flood hazards. In cases where the 1- and 0.2-percent-annual-chance floodplain boundaries are close together, only the 1-percent-annual-chance floodplain boundary has been shown. Small areas within the floodplain boundaries may lie above the flood elevations but cannot be shown due to limitations of the map scale and/or lack of detailed topographic data.

For the streams studied by Limited Detailed and Approximate methods, only the 1-percent-annual-chance floodplain boundary is shown on the FIRM (Exhibit 2).

### **4.2 Floodways**

Encroachment on floodplains, such as structures and fill, reduces flood-carrying capacity, increases flood heights and velocities, and increases flood hazards in areas beyond the encroachment itself. One aspect of floodplain management involves balancing the economic gain from floodplain development against the resulting increase in flood hazard. For purposes of the NFIP, a floodway is used as a tool to assist local communities in this aspect of floodplain management. Under this concept, the area of the 1-percent-annual-chance floodplain is divided into a floodway and a floodway fringe. The floodway is the channel of a stream, plus any adjacent floodplain areas, that must be kept free of encroachment so that the 1-percent-annual-chance flood can be carried without substantial increases in flood heights. Minimum Federal standards limit such increases to 1.0 foot, provided that hazardous velocities are not produced. The floodways

in this FIS are presented to local agencies as minimum standards that can be adopted directly or that can be used as a basis for additional floodway studies.

The floodways presented in this FIS report and on the FIRM were computed for certain stream segments on the basis of equal-conveyance reduction from each side of the floodplain. Floodway widths were computed at cross sections. Between cross sections, the floodway boundaries were interpolated. The results of the floodway computations have been tabulated for selected cross sections of detailed study streams in Table 7. The computed floodways are shown on the FIRM (Exhibit 2). In cases where the floodway and 1-percent-annual-chance floodplain boundaries are either close together or collinear, only the floodway boundary is shown.

Encroachment into areas subject to inundation by floodwaters having hazardous velocities aggravates the risk of flood damage, and heightens potential flood hazards by further increasing velocities. A listing of stream velocities at selected cross sections is provided in Table 7. In order to reduce the risk of property damage in areas where the stream velocities are high, the county may wish to restrict development in areas outside the floodway.

Near the mouths of streams studied in detail, floodway computations are made without regard to flood elevations on the receiving water body. Therefore, "Without Floodway" elevations presented in Table 7, "Floodway Data" for certain downstream cross sections of Gallagher Creek, Magnolia Creek, Okatibbee Creek, Robbins Branch, Shear's Branch, Harbour Creek, and Newell Branch are lower than the regulatory flood elevations in that area, which must take into account the 1-percent-annual-chance flood due to backwater from other sources.

The area between the floodway and 1-percent-annual-chance floodplain boundaries is termed the floodway fringe. The floodway fringe encompasses the portion of the floodplain that could be completely obstructed without increasing the water-surface elevation of the 1-percent-annual-chance flood more than 1.0 foot at any point. Typical relationships between the floodway and the floodway fringe and their significance to floodplain development are shown in Figure 1.

No floodways were computed for Okatibbee Creek Tributary 5, Nanabe Creek, Suqualena Creek, Harper Creek, Harper Creek Tributary 1, Loper Creek, Gunn Branch, and Bailey Branch.

## 5.0 INSURANCE APPLICATIONS

For flood insurance rating purposes, flood insurance zone designations are assigned to a community based on the results of the engineering analyses. These zones are as follows:

### Zone A

Zone A is the flood insurance rate zone that corresponds to the 1-percent-annual-chance floodplains that are determined in the FIS by approximate methods. Because detailed hydraulic analyses are not performed for such areas, no BFEs, or flood depths are shown within this zone.

### Zone AE

Zone AE is the flood insurance rate zone that corresponds to the 1-percent-annual-chance floodplains that are determined in the FIS by detailed methods. In most instances, whole-foot BFEs derived from the detailed hydraulic analyses are shown at selected intervals within this zone.

### Zone AH

Zone AH is the flood insurance rate zone that corresponds to the areas of 1-percent-annual-chance shallow flooding (usually areas of ponding) where average depths are between 1 and 3 feet. Whole-foot BFEs derived from the detailed hydraulic analyses are shown at selected intervals within this zone.

### Zone AO

Zone AO is the flood insurance risk zone that corresponds to the areas of the 1-percent-annual-chance shallow flooding (usually areas of ponding) where average depths are between 1 and 3 feet. Average whole-foot base flood depths derived from the detailed hydraulic analyses are shown within this zone.

### Zone V

Zone V is the flood insurance risk zone that corresponds to the 1-percent-annual-chance coastal floodplains that have additional hazards associated with storm waves. Because approximate hydraulic analyses are performed for such areas, no BFEs are shown within this zone.

### Zone VE

Zone VE is the flood insurance risk zone that corresponds to the 1-percent-annual-chance coastal floodplains that have additional hazards associated with storm waves. Whole-foot BFEs derived from the detailed hydraulic analyses are shown at selected intervals within this zone.

### Zone X

Zone X is the flood insurance rate zone that corresponds to areas outside the 0.2-percent-annual-chance floodplain, areas within the 0.2-percent-annual-chance floodplain, areas of 1-percent-annual-chance flooding where average depths are less than 1 foot, areas of

1-percent-annual-chance flooding where the contributing drainage area is less than 1 square mile, and areas protected from the base flood by levees. No BFEs or depths are shown within this zone.

#### Zone D

Zone D is the flood insurance rate zone that corresponds to unstudied areas where flood hazards are undetermined, but possible.

## **6.0 FLOOD INSURANCE RATE MAP**

The FIRM is designed for flood insurance and floodplain management applications.

For flood insurance applications, the map designates flood insurance rate zones as described in Section 5.0 and, in the 1-percent-annual-chance floodplains that were studied by detailed methods, shows selected whole foot BFEs or average depths. Insurance agents use the zones and BFEs in conjunction with information on structures and their contents to assign premium rates for flood insurance policies.

For floodplain management applications, the map shows by tints, screens, and symbols, the 1- and 0.2-percent-annual-chance floodplains, floodways, and the locations of selected cross sections used in the hydraulic analyses and floodway computations.

The countywide FIRM presents flooding information for the entire geographic area of Lauderdale County. Historical data relating to the maps prepared for each community are presented in Table 8, "Community Map History".

COMMUNITY NAME	INITIAL IDENTIFICATION	FLOOD HAZARD BOUNDARY MAP REVISIONS DATE	FIRM EFFECTIVE DATE	FIRM REVISIONS DATE
Marion, Town of	January 4, 1974	January 16, 1976 September 5, 1980	September 29, 1989	August 16, 1995 March 21, 2000
Meridian, City of	June 28, 1974	January 30, 1976	December 15, 1977	September 10, 1982 September 29, 1989 August 16, 1995 March 21, 2000
Lauderdale County (Unincorporated Areas)	January 13, 1978	NONE	September 29, 1989	August 16, 1995 March 21, 2000

**TABLE 8**

FEDERAL EMERGENCY MANAGEMENT AGENCY  
**LAUDERDALE COUNTY, MS**  
 AND INCORPORATED AREAS

**COMMUNITY MAP HISTORY**

## **7.0 OTHER STUDIES**

Information pertaining to revised and unrevised flood hazards for each jurisdiction within Lauderdale County has been compiled into this FIS. Therefore, this FIS supersedes all previously printed FIS reports, FIRMs, and/or FBFMs for all of the incorporated and unincorporated jurisdictions within Lauderdale County.

## **8.0 LOCATION OF DATA**

Information concerning the pertinent data used in the preparation of this study can be obtained by contacting Federal Insurance and Mitigation Division, FEMA Region IV, Koger-Center — Rutgers Building, 3003 Chamblee Tucker Road, Atlanta, GA 30341.
